Centrality Metrics

Dr. Natarajan Meghanathan
Professor of Computer Science
Jackson State University
E-mail: natarajan.meghanathan@jsums.edu
Centrality

• Tells us which nodes are important in a network based on the topological structure of the network (instead of using the offline information about the nodes: e.g., popularity of nodes)
  – How influential a person is within a social network
  – Which genes play a crucial role in regulating systems and processes
  – Infrastructure networks: if the node is removed, it would critically impede the functioning of the network.

Nodes X and Z have higher Degree

Node Y is more central from the point of view of
Betweenness – to reach from one end to the other
Closeness – can reach every other vertex in the fewest number of hops
Centrality Metrics

• Degree-based Centrality Metrics
  – **Degree Centrality**: measure of the number of vertices adjacent to a vertex (degree)
  – **Eigenvector Centrality**: measure of the degree of the vertex as well as the degree of its neighbors

• Shortest-path based Centrality Metrics
  – **Betweenness Centrality**: measure of the number of shortest paths a node is part of
  – **Closeness Centrality**: measure of how close is a vertex to the other vertices [sum of the shortest path distances]
  – **Farness Centrality**: captures the variation of the shortest path distances of a vertex to every other vertex

• Hybrid Centrality Metrics
  – **Local Clustering Coefficient based Degree Centrality**: Nodes having a lower local clustering coefficient, but larger degree, lie on the shortest paths for several of their neighbor nodes.
Degree Centrality

Weakness: Very likely that more than one vertex has the same degree and not possible to uniquely rank the vertices

Time Complexity: $\Theta(V^2)$
Eigenvector Centrality (1)

Power Iteration Method

Time Complexity: $\Theta(V^3)$
Eigenvector Centrality (2)

After 7 iterations

Principal Eigenvalue

$$\eta_1 = 16.315$$

Time Complexity: $$\Theta(VE + V^2)$$
Betweeness Centrality

\[ BWC(i) = \sum_{j \neq k \neq i} \frac{sp_{jk}(i)}{sp_{jk}} \]

Time Complexity: \( \Theta(VE + V^2) \) (\( j < k \) for undirected graphs)

- We will now discuss how to find the total number of shortest paths between any two vertices \( j \) and \( k \) as well as to find out how many of these shortest paths go through a vertex \( i \) (\( j \neq k \neq i \)).
- Use Breadth First Search (BFS) to find the shortest path tree from vertex \( j \) to every other vertex \( k \)
  - Root vertex \( j \) is at level 0
  - Vertices that are 1-hop away from \( j \) are at level 1; 2-hops away from \( j \) are at level 2, and so on.
  - The number of shortest paths from \( j \) to a vertex \( k \) at level \( p \) is the sum of the number of shortest paths from \( j \) to the neighbors of \( k \) in the original graph that are at level \( p-1 \)
  - The number of shortest paths from \( j \) to \( k \) that go through vertex \( i \) is the maximum of the number of shortest paths from \( j \) to \( i \) and the number of shortest paths from \( k \) to \( i \).

For vertices 1, 6 and 7 BWC = 0

### Betweenness for Vertex 0
- Pair (3, 1) --> 1 / 2
- Pair (4, 1) --> 1 / 2
- Pair (5, 1) --> 1 / 2
- Pair (6, 1) --> 1 / 2
- Pair (7, 1) --> 1 / 2
- Total of all Betweenness (Vertex 0): 2.5

### Betweenness for Vertex 2
- Pair (3, 1) --> 1 / 2
- Pair (4, 1) --> 1 / 2
- Pair (5, 1) --> 1 / 2
- Pair (6, 1) --> 1 / 2
- Pair (7, 1) --> 1 / 2
- Total of all Betweenness (Vertex 2): 2.5

### Betweenness for Vertex 3
- Pair (4, 0) --> 1 / 1
- Pair (5, 0) --> 1 / 1
- Pair (6, 0) --> 1 / 1
- Pair (7, 0) --> 1 / 1
- Pair (4, 1) --> 2 / 2
- Pair (5, 1) --> 2 / 2
- Pair (6, 1) --> 2 / 2
- Pair (7, 1) --> 2 / 2
- Pair (7, 1) --> 2 / 2
- Total of all Betweenness (Vertex 3): 12

### Betweenness for Vertex 5
- Pair (6, 0) --> 1 / 1
- Pair (7, 0) --> 1 / 1
- Pair (6, 1) --> 2 / 2
- Pair (7, 1) --> 2 / 2
- Pair (6, 2) --> 1 / 1
- Pair (7, 2) --> 1 / 1
- Pair (6, 3) --> 1 / 1
- Pair (7, 3) --> 1 / 1
- Pair (6, 4) --> 1 / 1
- Pair (7, 4) --> 1 / 1
- Total of all Betweenness (Vertex 5): 10

### Betweenness for Vertex 4
- Pair (5, 0) --> 1 / 1
- Pair (6, 0) --> 1 / 1
- Pair (7, 0) --> 1 / 1
- Pair (5, 1) --> 2 / 2
- Pair (6, 1) --> 2 / 2
- Pair (7, 1) --> 2 / 2
- Pair (5, 2) --> 1 / 1
- Pair (6, 2) --> 1 / 1
- Pair (7, 2) --> 1 / 1
- Pair (5, 3) --> 1 / 1
- Pair (6, 3) --> 1 / 1
- Pair (7, 3) --> 1 / 1
- Total of all Betweenness (Vertex 4): 12
# shortest paths from a to g that go through c is the maximum (# shortest paths from a to c, # shortest paths from g to c) = \text{max} (2, 1) = 2

BWC ('c' with respect to pair a-g) = 2/4

Levels of Vertices on the BFS tree

# shortest paths from the root to the other vertices
To determine how many Shortest paths from nodes 1 to 7 that go through node 4.
To determine how many Shortest paths from nodes 1 to 7 that go through node 4: \(= \text{Max}(2, 1) = 2\)

\[\text{BWC(node 4 with respect to pair 1-7) = 2/2}\]
Ego Network

- The ego network is node-specific.
- The ego network for a node comprises of the node and its neighbors as vertices and the links connecting the node and/or its neighbors as edges.
- The BWC of a vertex computed on the entire graph is directly related to the LCCDC of the vertex computed on its ego network (see next few slides).
  - Could be used to rank the vertices.
Local Clustering Coefficient-based Degree Centrality (LCCDC)

- Local Clustering Coefficient (LCC) of a node is the ratio of the number of edges connecting the neighbors of the node to that of the maximum number of edges between the neighbors of the node.
- A node having a lower LCC and a larger degree is more likely needed to connect its neighbor nodes on the shortest path, compared to that of a node having a larger LCC and a larger degree.
- LCCDC \( (v) = (1 – \text{LCC}(v)) \times \text{degree}(v) \)
- LCCDC can be used as an alternate metric for ranking the vertices in a graph in lieu of BWC.
- The LCCDC metric for a vertex can also be computed on the egocentric network graph of the vertex.

A maximum of \( 4(4-1)/2 = 6 \) edges is possible among the neighbors of node 2.
There are actually 2 edges among the neighbors.
LCC(2) = 2/6 = 1/3.
Degree(2) = 4.
LCCDC(2) = \([1 – \text{LCC}(2)] \times \text{Degree}(2)\)  
\[= [1 – 1/3] \times 4 = 8/3 = 2.67. \]

Spearman’s Rank-based Correlation

• We could find the similarity of the ranking of the vertices in a graph with respect to two different centrality metrics using the Spearman’s rank-based correlation measure.

• We follow the convention of assigning the rank values from 1 to \( n \) for a graph of \( n \) vertices, even though the vertex IDs range from 0 to \( n-1 \).

• To obtain the rank for a vertex based on the list of values for a centrality metric, we first sort the values (in ascending order).
  – If there is any tie, we break the tie in favor of the vertex with a lower ID; we will thus be able to arrive at a tentative, but unique, rank value for each vertex with respect to the centrality metric.

• We determine a final ranking of the vertices as follows:
  – For vertices with unique value of the centrality metric, the final ranking is the same as the tentative ranking.
  – For vertices with an identical value for the centrality metric, the final ranking is assigned to be the average of their tentative rankings.
Spearman’s Rank-based Correlation

\[ SCC(B, L) = 1 - \frac{6 \sum_{i=1}^{n} d_i^2}{n(n^2 - 1)} \]

\( d_i \) is the difference in the final ranking for vertex \( i \) in the two datasets

Correlation Coefficient = \( 1 - \frac{6 \times 2}{8 \times (8^2 - 1)} \) = 0.98
Concordant, Discordant Pairs

• Let B and L be the two centrality metrics of interest.

• For any two vertices vi and vj:
  – vi and vj are concordant if:
    • B(vi) > B(vj) and L(vi) > L(vj)
    • B(vi) < B(vj) and L(vi) < L(vj)
    • B(vi) = B(vj) and L(vi) = L(vj)
  – vi and vj are discordant if:
    • B(vi) > B(vj) and L(vi) < L(vj)
    • B(vi) < B(vj) and L(vi) > L(vj)

Kendall’s Concordance based Correlation Coefficient

\[ KCC(B, L) = \frac{\#conc.pairs - \#disc.pairs}{\frac{1}{2} n(n-1)} \]

KCC = \((27 – 1)/28\) = 0.93
Link Analysis-based Ranking

• We want to rank a node in a graph based on the number of edges pointing to it and/or leaving it as well as based on the rank of the nodes at the other end of these edges.

• Used primarily in web search
  – We model the web as a graph: the pages as nodes and the edges are directed edges – a page citing (having a link to) another page.

• Hubs and Authorities (HITS) algorithm
• PageRank algorithm
Hypertext Induced Topic Search (HITS) Algorithm

- **Hub**: Node that points to lots of pages
  - Yahoo like directory
- **Authority**: Node to which several other nodes point to
  - The larger the number of nodes pointing to a node, the more authoritative is the view presented by a node on a particular subject
- The HITS algorithm assigns **two scores for each page**:
  - **Authority**: an estimate of the value of the contents of the page
  - **Hub**: an estimate of the value of its links to other pages

- A page is considered to be **more authoritative** if it is referenced by many hub pages that are relevant to a search query
- A page is a **hub page** for a search query if it points to many authoritative pages for that query
- Good **authoritative** and **hub** pages reinforce one another.

A variant of HITS is used by Ask.com
Finding Pages for a Query in HITS

• **Initial Work**
  - Step 1: Submit query $q$ to a similarity-based engine and record the top $n$, i.e., the root set $RS(q)$ pages.
  - Step 2: Expand set $RS(q)$ into the base set $BS(q)$ to include pages pointed by $RS(q)$ pages.
  - Step 3: Also include into $BS(q)$, the pages pointing to $RS(q)$ pages.

• **Run the HITS algorithm**
  - For each page $pj$, compute the authority and hub score of $pj$ through a sequence of iterations.

• **After obtaining the final authority and hub scores** for each page, display the search results in the decreasing order of the authority scores. Pages having zero authority scores (nodes with no incoming links – strictly hubs) are listed in the decreasing order of their hub scores.
  - Note: nodes that are strictly hubs still contribute to the authority of the nodes that it points to.
HITS Algorithm

• Let E be the set of links in BS(q) and a link from page pi to pj is denoted by the pair (i, j).

• **A: Authority Update Step**

\[
a(p_j) = \sum_{(i,j) \in E} h(p_i)
\]

• The authority values at iteration \(i\) are using the authority values just computed in iteration \(i\) (rather than iteration \(i - 1\)).

• **H: Hub Update Step**

\[
h(p_j) = \sum_{(j,k) \in E} a(p_k)
\]

• After each iteration \(i\), we scale the ‘a’ and ‘h’ values:

\[
a^{(i)}(p_j) = \frac{a^{(i)}(p_j)}{\sqrt{\sum_k (a^{(i)}(p_k))^2}}
\]

\[
h^{(i)}(p_j) = \frac{h^{(i)}(p_j)}{\sqrt{\sum_k (h^{(i)}(p_k))^2}}
\]

• As can be noted above, the two steps are interwined: one uses the values computed from the other.
  – In this course, we will follow the asynchronous mode of computation, according to which the authority values are updated first for a given iteration \(i\) and then the hub values are updated.
  • The hub values at iteration \(i\) are using the authority values just computed in iteration \(i\) (rather than iteration \(i - 1\)).

</table>
PageRank

• The basic idea is to analyze the link structure of the web to figure out which pages are more authoritative (important) in terms of quality.
• It is a content-independent scheme.
• If Page A has a hyperlink to Page B, it can be considered as a vote of A for B.
  – If multiple pages link to B, then page B is likely to be a good page.
• A page is likely to be good if several other good pages link to it (a bit of recursive definition).
  – Not all pages that link to B are of equal importance.
  – A single link from CNN or Yahoo may be worth several times
• The web pages are first searched based on the content. The retrieved web pages are then listed based on their rank (computed on the original web, unlike HITS that is run on a graph of the retrieved pages).
• The Page Rank of the web pages are indexed (recomputed) for every regular time period.
PageRank
(Random Web Surfer)

- Web – graph of pages with the hyperlinks as directed edges.
- Analogy used to explain PageRank algorithm (Random Web Surfer)
- User starts browsing on a random page
- Picks a random out-going link listed in that page and goes there (with a probability ‘d’, also called damping factor)
  - Repeated forever
- The surfer jumps to a random page with probability 1-d.
  - Without this characteristic, there could be a possibility that someone could just end up oscillating between two pages B and C as in the traversing sequence below for the graph shown aside:
    G → E → F → E → D → B → C

Let’s say d = 0.85. To decide the next page to move, the surfer simply generates a random number, r. If r <= 0.85, then the surfer randomly chooses an out-going link from the existing page. Otherwise, jumps to a randomly chosen page among all the pages, including the current page.
PageRank Algorithm

• PageRank of Page X is the probability that the surfer is at page X at a randomly selected time.
  – Basically the proportion of time, the surfer would spend at page X.

• **PageRank Algorithm**
  
  • **Initial**: Every node in the graph gets the same pagerank. \( PR(X) = \frac{100\%}{N} \), where \( N \) is the number of nodes.

  • At any time, at the end of each iteration, the page rank of all nodes add up to 100%.

  • Actually, the initial pagerank value of a node is the pagerank at any time, if there are no edges in the graph. We have \( \frac{100\%}{N} \) chance of jumping to any node in the graph at any time.

*Initial PageRank of Nodes*
Page Rank of Node X is the probability of being at node X at the current time.

How can we visit node X from where we are?

- **(1-d) term: Random Jump:** The probability of ending up at node X because of a random jump from some node, including node X, is 1/N.
  - However, such a random jump itself could occur with a probability of (1-d).
  - This amounts to a probability of (1-d)/N to be at node X due to a random jump.

\[
PR(x) = \frac{(1-d) \times 100}{N} + d \sum_{y \rightarrow x} \frac{PR(y)}{Out(y)}
\]

Assuming there are NO Sink nodes
Page Rank of Node X is the probability of being at node X at the current time.

How can we visit node X from where we are?

- **d term: Edge Traversal from a Neighbor:**
  - We could visit node X from one of the nodes that point to node X.
  - Let's say, we are at node Y in the previous iteration. The probability of being at node Y in the previous iteration is PR(Y). We can visit any of Y's neighbors.
  - The probability of visiting node X among the Out(Y) out-going links of node Y is PR(Y) * (1 / Out(Y)) = PR(Y) / Out(Y).
  - Likewise, we could visit X from any of its neighbors.
  - All the probabilities of visiting X from any of its neighbors have to be added, because visiting X from any of its neighbors is independent of the neighbors.
  - The whole event of visiting from a neighbor occurs with a prob. 'd'

\[
PR(x) = \frac{(1-d) \times 100}{N} + d \sum_{y \rightarrow x} \frac{PR(y)}{Out(y)}
\]
PageRank

• Since Page Rank PR(X) denotes the probability of being at node X at any time, the sum of the Page Ranks of all the nodes at any time should be equal to 1.

• We can also interpret the traversal from a node Y to node X as node Y contributing a part of its PR to node X (node Y equally shares its PR to the nodes connected to it through its out-going links).

• Implementation:
  – Note that (unlike HITS) we need to use the page rank values of the nodes from the previous iteration to update the page rank values of the nodes in the current iteration.
    • Need to maintain two arrays at any time t: PR(t-1) and PR(t)
Calculating PageRank of Node B

Assume the damping factor $d = 0.85$

For any iteration,

$$\text{PR}(B) = 0.15 \times 9.1 + 0.85 \times \left[ \text{PR}(C) + \frac{1}{2} \text{PR}(D) + \frac{1}{3} \text{PR}(E) + \frac{1}{2} \text{PR}(F) + \frac{1}{2} \text{PR}(G) + \frac{1}{2} \text{PR}(H) + \frac{1}{2} \text{PR}(I) \right]$$

For Iteration 1, Substituting the PR values of the nodes (initial values), we get $\text{PR}(B) \approx 31$
Final PageRank Values for the Sample Graph
PageRank: More Observations

• Algorithm converges (few iterations sufficient)
• For an arbitrary graph, it is pretty difficult to figure out the final page rank values of the nodes.
• Certain inferences could be however made.
• For our sample graph:
  – For nodes that do not have any in-links pointing to them, the only way we will end up at these nodes is through a random jump: this happens with a probability \((1-d)/N\). In our case, it is \((1-0.85) \times 100/11 = 1.6\%\).
  – Two nodes with links from the same node (symmetric in-links) have the same PR. (nodes D and F) and it will be higher than those nodes without any in-links.
  – One in-link from a node with high PR value contributes significantly to the PR value of a node compared to the in-links from several low PR nodes.
    • In our sample graph, an in-link from node B contributes significantly for node C compared to the several in-links that node E gets from the low-PR nodes. So, the quality of the in-links matters more than the number of in-links.
Note that there are NO sink nodes (nodes without any out-going links)

Assume damping Factor $d = 0.85$

$$PR(A) = (1-d) \times 100/4$$
$$PR(B) = (1-d) \times 100/4 + d \times [PR(A) + 1/2 \times PR(C) + PR(D)]$$
$$PR(C) = (1-d) \times 100/4 + d \times [PR(B)]$$
$$PR(D) = (1-d) \times 100/4 + d \times [1/2 \times PR(C)]$$

Node Ranking: A B C D
Motivating Example

Consider the graph: A → B
Let \( d = 0.85 \)

\[
\begin{align*}
PR(A) &= 0.15 \times 100 / 2 \\
PR(B) &= 0.15 \times 100 / 2 + 0.85 \times PR(A)
\end{align*}
\]

Initial: \( PR(A) = 50 \), \( PR(B) = 50 \)

Iteration 1:
- \( PR(A) = 0.15 \times 100 / 2 = 7.5 \)
- \( PR(B) = 0.15 \times 100 / 2 + 0.85 \times 50 = 50.0 \)
- \( PR(A) + PR(B) = 57.5 \)
- Note that the PR values do not add up to 100.
- This is because, B is not giving back the PR that it receives from A to any other node in the graph. The \( 0.85 \times 50 = 42.5 \) value of PR that B receives from A is basically lost.
- Once we get to B, there is no way to get out of B other than random jump to A and this happens only with probability \( (1-d) \).
Page Rank: Sink Nodes (Solution)

- Assume implicitly that the sink node is connected to every node in the graph (including itself).
  - The sink node equally shares its PR with every node in the graph, including itself.
  - If $z$ is a sink node, with the above scheme, $\text{out}(z) = N$, the number of nodes in the graph.

- The probability of getting to node X at a given time is still the two terms below:
  - Random jump from any node (probability, $1-d$)
  - Visit from a node with in-link to node X (probability, $d$)

\[
PR(x) = \frac{(1-d) \times 100}{N} + d \sum_{y \rightarrow x} \frac{PR(y)}{\text{Out}(y)} + d \sum_{z \rightarrow \varphi} \frac{PR(z)}{N}
\]

Explicit out-going links to certain nodes
Implicit out-going links to all nodes (sink nodes)

the second term of the original Page Rank formula is now broken between that of nodes with explicit out-going links to one or more selected nodes and the sink nodes with implicit out-going links to all nodes.
**Consolidated PageRank Formula**

\[
PR(x) = \frac{(1-d) \times 100}{N} + d \sum_{y \rightarrow x} \frac{PR(y)}{Out(y)} + d \sum_{z \rightarrow x} \frac{PR(z)}{N}
\]

**Page Rank Example (3)**

- Initial PR(A) 25 PR(B) 25 PR(C) 25 PR(D) 25
- It # 1 PR(A) 48.02 PR(B) 16.15 PR(C) 26.77 PR(D) 9.063
- It # 2 PR(A) 46.14 PR(B) 16.52 PR(C) 23.386 PR(D) 13.954
- It # 3 PR(A) 44.41 PR(B) 17.51 PR(C) 24.53 PR(D) 13.55
- It # 4 PR(A) 45.32 PR(B) 17.03 PR(C) 24.47 PR(D) 13.18

Node Ranking: A, C, B, D
Page Rank Example (4)

PR(A) = 0.15*100/4 + 0.85*{PR(B)/4}
PR(B) = 0.15*100/4 + 0.85*{PR(A) + PR(C)/2 + PR(D)} +
       0.85*{PR(B)/4}
PR(C) = 0.15*100/4 + 0.85*{PR(B)/4}
PR(D) = 0.15*100/4 + 0.85*{PR(C)/2} + 0.85*{PR(B)/4}

| Rank | The example shows that though both A and C differ with respect to the number of outgoing edges, their Page Rank value is the same. | B | D | A, C | The Page Rank of a vertex is dependent only on the incoming edges and where they are from. |
