

Community Detection Algorithms

Dr. Natarajan Meghanathan
Professor of Computer Science
Jackson State University, Jackson, MS
E-mail: natarajan.meghanathan@jsums.edu

Community

- Community: It is formed by individuals such that those within a group interact with each other more frequently than with those outside the group.
- Community detection: discovering groups in a network where individuals' group memberships are not explicitly given.
 - Interactions (edges) between nodes can help determine communities
- Community structures are quite common in real networks. Social networks include community groups based on common location, interests, occupation, etc.
- Metabolic networks have communities based on functional groupings.
- Citation networks form communities by research topic.
- Identifying the community sub structures within a network can provide insight into how network function and topology affect each other.

There is most likely a path from one vertex to another vertex within a community through the vertices that are also part of the same community.

For the Karate Club network (to the left), the internal densities of the two communities are 0.26 and 0.24; the external densities are 0.035; the overall network density is 0.14.

Internal and External Community Densities

- Let C be a subset of nodes (V) that form a community.
- For every node i in C , let k_i^{int} and k_i^{ext} be the # links connecting node i to a node in C and outside C respectively.

$$\delta_{int}(C) = \frac{\sum_i k_i^{int}}{n_C(n_C - 1)}$$

$$\delta_{ext}(C) = \frac{\sum_i k_i^{ext}}{2n_C(n_C - 1)}$$

The internal density of every cluster is significantly larger than the external density as well as the total density of the network.

Internal Densities

C1	$(4*3 + 1*4) / (5*4) = 0.8$
C2	$(6*5)/(6*5) = 1.0$
C3	$(4*3)/(4*3) = 1.0$

External Densities

C1	$(1 + 1) / (2*5*4) = 0.05$
C2	$(1 + 1 + 1 + 1)/(2*6*5) = 0.067$
C3	$(1 + 1)/(2*4*3) = 0.083$

Schemes for Identifying Communities

- The number of communities within a network is typically unknown and the communities are often of unequal size and/or density.
- Schemes:
 - Hierarchical Clustering
 - Bottom-up and Top-down
 - Neighborhood Overlap based
 - Weak-ties based
 - Homophily
 - Eigen Vector based
- Evaluation:
 - Modularity Maximization

Modularity Maximization

Modularity Maximization

- Modularity measures the strength of a community partition by taking into account the degree distribution.
- Given a network with m edges, the expected number of edges between two nodes i and j with degrees d_i and d_j respectively is $d_i d_j / 2m$.

Expected number of edges between nodes 1 and 2 is $(3)(2) / (2 \cdot 15) = 0.20$

Strength of a Community, C

$$\sum_{i \in C, j \in C} A_{i,j} - \frac{d_i d_j}{2m}$$

For a network with k communities and a total of m edges

Modularity:

$$Q = \sum_{l=1}^k \sum_{i \in C_l, j \in C_l} A_{i,j} - \frac{d_i d_j}{2m}$$

A larger value for Q indicates a good community structure

Modularity Maximization

- The intuition behind the idea of modularity is that a community is a structural element of a network that has been formed in a manner far from a random process.
- If we consider the actual density of links in a community, it should be significantly larger than the density we would expect if the links in the network were formed by a random process.
 - In other words, if two nodes i and j end up being in the same community, there should be more likely a link between them (i.e., $A_{ij} = 1$, leading to an overall high value for Q).
 - If i and j end up being in a community such that the chances of having a link between them is just as the same as between any two nodes in the network (i.e., a random network), then the value of Q is more likely to be low (because there could be some $A_{ij} = 0$ that will bring down the value of Q).

Evaluating Modularity (Example 1)

Community [1, 4, 5, 7]

Edges with $A_{ij} = 1$ Modularity

1 – 4 $1 - (3)(4)/(2 \cdot 15) = 0.60$

4 – 5 $1 - (4)(5)/(2 \cdot 15) = 0.33$

5 – 7 $1 - (3)(5)/(2 \cdot 15) = 0.50$

Edges with $A_{ij} = 0$

1 – 5 $0 - (3)(5)/(2 \cdot 15) = -0.50$

1 – 7 $0 - (3)(3)/(2 \cdot 15) = -0.30$

4 – 7 $0 - (4)(3)/(2 \cdot 15) = -0.40$

Total Modularity Score for Community [1, 4, 5, 7] **0.23**

Total Modularity for the two Communities: $0.23 + 0.23 = 0.46$

Community [2, 3, 6, 8]

Edges with $A_{ij} = 1$ Modularity

2 – 3 $1 - (3)(4)/(2 \cdot 15) = 0.60$

2 – 6 $1 - (3)(5)/(2 \cdot 15) = 0.50$

6 – 8 $1 - (3)(5)/(2 \cdot 15) = 0.50$

Edges with $A_{ij} = 0$

2 – 8 $0 - (3)(3)/(2 \cdot 15) = -0.30$

3 – 6 $0 - (4)(5)/(2 \cdot 15) = -0.67$

3 – 8 $0 - (4)(3)/(2 \cdot 15) = -0.40$

Total Modularity Score for Community [2, 3, 6, 8] **0.23**

Evaluating Modularity (Example 2)

Community [1, 2, 3, 4]

Edges with $A_{ij} = 1$ Modularity

1 – 2	$1 - (3)(3)/(2*15) = 0.70$
1 – 3	$1 - (3)(4)/(2*15) = 0.60$
1 – 4	$1 - (3)(4)/(2*15) = 0.60$
2 – 3	$1 - (3)(3)/(2*15) = 0.70$
3 – 4	$1 - (4)(4)/(2*15) = 0.47$

Edges with $A_{ij} = 0$

2 – 4	$0 - (3)(4)/(2*15) = -0.40$
-------	-----------------------------

Total Modularity Score for Community [1, 2, 3, 4] 2.67

Total Modularity for the two Communities: $2.67 + 2.87 = 5.54$

Community [5, 6, 7, 8]

Edges with $A_{ij} = 1$ Modularity

5 – 6	$1 - (5)(5)/(2*15) = 0.17$
5 – 7	$1 - (3)(5)/(2*15) = 0.50$
5 – 8	$1 - (3)(5)/(2*15) = 0.50$
6 – 7	$1 - (3)(5)/(2*15) = 0.50$
6 – 8	$1 - (3)(5)/(2*15) = 0.50$
7 – 8	$1 - (3)(3)/(2*15) = 0.70$

Total Modularity Score for Community [2, 3, 6, 8] 2.87

Hierarchical Clustering (Complete Linkage Clustering)

Bottom-Up Approach
(Agglomerative)

Complete Linkage Clustering

- Compute the “pair-wise” distance matrix P between any two vertices.
- Initially, start with each vertex in its own cluster.
- Merge the two “closest” vertices (clusters)
 - In case of a tie (between two cluster-cluster pairs or between two cluster-vertex pairs), choose the pair with the minimum value for the total pair-wise distance / sum of the two pair sizes
 - In case of a tie between a cluster-vertex pair and a vertex-vertex pair, choose the cluster-vertex pair
 - In case of a tie between two vertex-vertex pairs, break the tie arbitrarily.
- Remove the entries from P, for the two vertices (clusters) merged, and add an entry corresponding to the merged vertex (cluster).
 - Update this entry with the longest distance between any vertex in the merged cluster with the vertices in the other clusters in P.

$$\text{Distance}(C_i, C_j) = \text{Max} \left[\bigvee_{u \in C_i} \bigvee_{v \in C_j} \text{MinHops}(u, v) \right]$$

- Repeat the above step of merging and removing/adding entries to P until there is only one cluster.

Complete Linkage Clustering (Example 1)

	1	2	3	4	5	6
1	0	1	1	2	2	3
2		0	1	1	2	2
3			0	2	1	2
4				0	2	1
5					0	1
6						0

	1,2	3	4	5	6

Complete Linkage Clustering

From the previous slides,
We know that the optimal
Partitioning of the graph is:

Modularity (1, 2, 3, 4) +
Modularity (5, 6, 7, 8) = 5.54

Thus, complete linkage clustering need not always give the optimal solution.

Hierarchical Clustering Edge Betweenness

Top-Down Approach
(Divisional)

Edge Betweenness

- Edge Betweenness (EdgeBW) is a measure of the number of shortest paths the edge is part of
 - To be exact, it is the sum of the fraction of the shortest paths going through the edge between any two vertices.

Example 1

Each fraction is $1/\text{number of paths for the pair}$

Pair	Paths	Edges			
		1-2	1-3	2-4	3-4
1, 2:	1-2	1/1			
1, 3:	1-3		1/1		
1, 4:	1-2-4, 1-3-4	1/2	1/2	1/2	1/2
2, 3:	2-1-3, 2-4-3	1/2	1/2	1/2	1/2
2, 4:	2-4			1/1	
3, 4:	3-4				1/1
EdgeBW (sum fractions)		2.0	2.0	2.0	2.0

Edge Betweenness

Example 2

Each fraction is 1/number of paths for the pair

Pair	Paths	1-2	1-4	2-3	2-5	3-6	4-5	5-6
1, 2	1-2	1/1						
1, 3	1-2-3	1/1		1/1				
1, 4	1-4		1/1					
1, 5	1-2-5 1-4-5	1/2	1/2		1/2		1/2	
1, 6	1-2-3-6 1-4-5-6 1-2-5-6	1/3	1/3	1/3	1/3	1/3		1/3
2, 3	2-3			1/1				
2, 4	2-1-4 2-5-4	1/2	1/2		1/2		1/2	
2, 5	2-5				1/1			
2, 6	2-3-6 2-5-6			1/2	1/2	1/2		1/2
Sum (partial)		3.67	2.33	2.83	2.83	0.83	1.33	1.17

Edge Betweenness

Example 2 (continued...)

Pair	Paths	1-2	1-4	2-3	2-5	3-6	4-5	5-6
	Sum (partial)	3.67	2.33	2.83	2.83	0.83	1.33	1.17
3, 4	3-2-1-4	1/3	1/3	1/3				
	3-6-5-4					1/3	1/3	1/3
	3-2-5-4			1/3	1/3		1/3	
3, 5	3-2-5			1/2	1/2			
	3-6-5					1/2		1/2
3, 6	3-6					1/1		
4, 5	4-5						1/1	
4, 6	4-5-6						1/1	1/1
5, 6	5-6							1/1
EdgeBWC (Sum)		4.0	2.67	4.0	3.67	2.67	4.0	4.0

Edge Betweenness

- Edge Betweenness (EdgeBW) is a measure of the number of shortest paths the edge is part of: sum of the fraction of the shortest paths going through the edge between any two vertices.
- Note that in this graph below, there is only one shortest path between any two nodes. Hence, the EdgeBW is simply the # shortest paths through that edge

Example 3

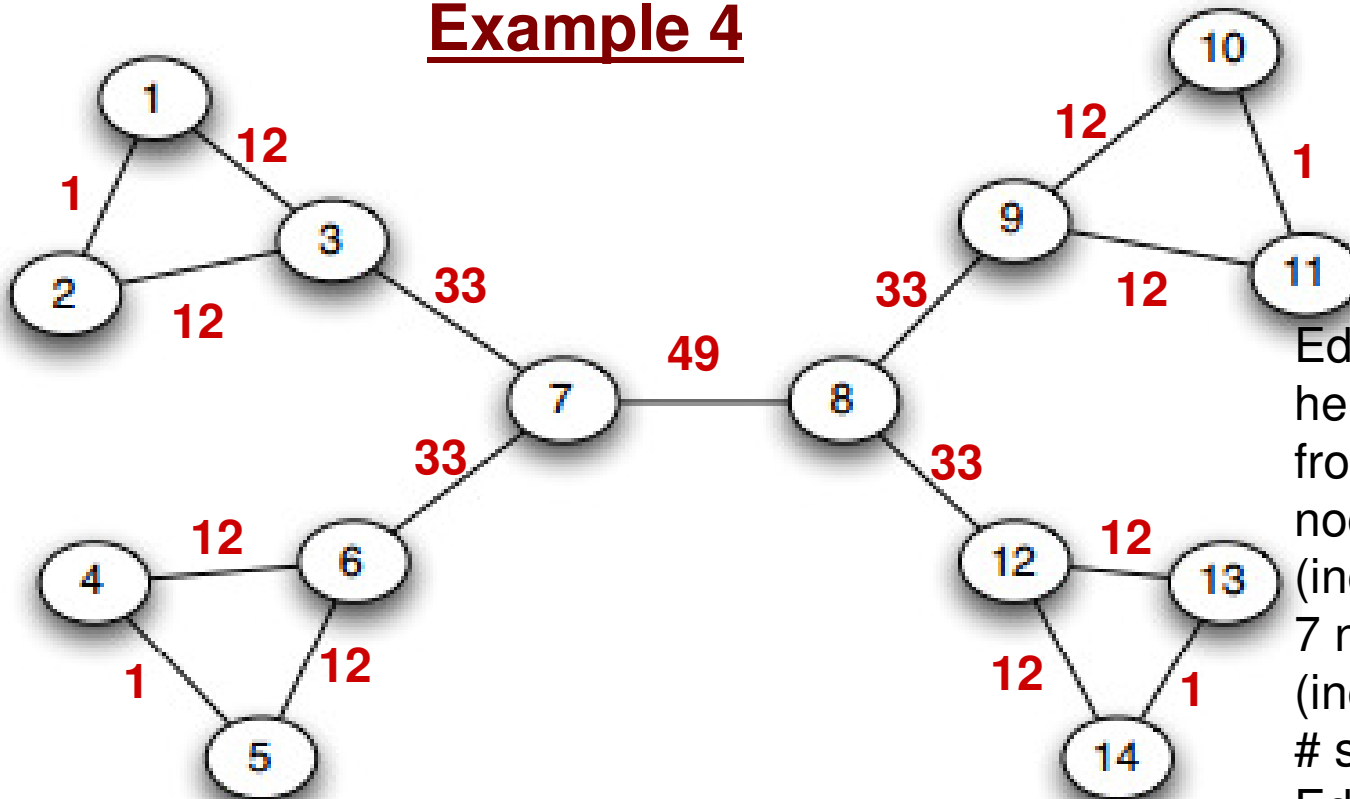

Pair	Paths	Edges				
		1-2	2-3	2-4	2-5	5-6
1, 2	1-2	1/1				
1, 3	1-2-3	1/1	1/1			
1, 4	1-2-4	1/1		1/1		
1, 5	1-2-5	1/1			1/1	
1, 6	1-2-5-6	1/1			1/1	1/1
2, 3	2-3		1/1			
2, 4	2-4			1/1		
2, 5	2-5				1/1	
2, 6	2-5-6				1/1	1/1
3, 4	3-2-4		1/1	1/1		
3, 5	3-2-5		1/1		1/1	
3, 6	3-2-5-6		1/1		1/1	1/1
4, 5	4-2-5			1/1	1/1	
4, 6	4-2-5-6			1/1	1/1	1/1
5, 6	5-6					1/1
EdgeBW (Sum)		5.0	5.0	5.0	8.0	5.0

Edge Betweenness

- Edge Betweenness (EdgeBW) is a measure of the number of shortest paths the edge is part of: sum of the fraction of the shortest paths going through the edge between any two vertices.
- Note that in this graph below, there is only one shortest path between any two nodes. Hence, the EdgeBW is simply the # shortest paths through that edge

Example 4

Edge 7-8 in the graph here carries info from each of the 7 nodes on the left (incl. node 7) and the 7 nodes on the right (incl. node 8)
shortest paths through Edge 7-8 is $7 \cdot 7 = 49$

Finding the # Shortest Paths through an Edge

- For graphs in which there is more than one paths between one or more pair of vertices, the total betweenness of an edge is not equal to the total # shortest paths through the edge.
- We will now see an algorithm proposed by Girvan and Newman to determine the total betweenness of an edge.
- Repeat the following for every vertex
 - Perform a Breadth First Search (BFS) of the graph, starting from the first vertex, say A.
 - Determine the # shortest paths from A to each other node using the BFS levels of the nodes
 - Based on the above numbers of shortest paths, determine the amount of info from A to all the other vertices that uses each edge.
- The total betweenness through an edge is the sum (for directed graph) or half of the sum (for undirected graph) of the betweenness determined through that edge when BFS is run from every vertex in the graph.
 - For undirected graph, we divide by the total sum of the BWs by 2 because an edge is counted twice on the shortest path between any two vertices.
 - For example $A - B - C$; the edge $A - B$ is counted twice (once on the shortest path from A to C and once on the shortest path from C to A)

BFS run on A

Node Levels

Computing the Fraction of Shortest Path Values

We assume one unit of info originates at each node. We start with the node at the bottom most level. Let 1 unit of info start from node D. Node D gets 2 of its Shortest paths to node A through F and 1 through G. So, node D sends $\frac{2}{3}$ of the info to F and $\frac{1}{3}$ through G. Node F adds $\frac{2}{3}$ info received to 1 unit of info originating at itself and splits the resulting 1.67 equally and sends 0.835 to each of B and E. G merely adds the 0.33 info units to the 1 units of info originating at itself and sends 1.33 to B.

Girvan-Newman (GN) Algorithm

- Proceeds in iterations
- At the beginning of each iteration, we compute the Betweenness of the edges in the graph and remove the edge(s) with the largest betweenness.
 - If more than one edge has the largest betweenness, remove all such competing edges at the same time.
 - If the graph gets disconnected to two or more communities (components), we compute the total modularity score of the resulting communities
- Repeat the iterations until there are no more edges
- The partition (set of communities) with the total modularity score is the optimal partition.
- **We could stop dividing a community if the total modularity score of the undivided community is greater than the total modularity score of the divided community.**
- **You could use the Java program (EdgeBWC.java) given to you to compute the betweenness of the edges in each iteration.**
- **You could use the Java program (PairwiseModularity.java) given to you to compute the modularity scores of the pairs of vertices in the original graph and use these scores in your modularity calculations for each iteration.**

GN Algorithm: Example 1

GN Algorithm: Example 1 (It # 1)

After removing edge 7-8 with the largest BW (49)

$$\text{Modularity}(4, 7) = 0.68$$

$$\text{Total Modularity Score} = 3.70$$

GN Algorithm: Example 5 (2)

Analysis of: Girvan and Newman Algorithm

- After we find the betweenness of the edges, we remove the edge with the largest betweenness.
- We re-run BFS on each vertex and find the betweenness of every edge and remove the edge with the largest betweenness henceforth.
- We repeat this process until we divide the graph into individual vertices.
- We keep track of the communities that get generated with each edge removal and then decide on the level of partition (to stop the edge removal process) by evaluating the modularity scores of the community scores formed at different levels.
- The Girvan and Newman algorithm, though effective in delineating communities with high modularity scores, is very inefficient as it requires BFS (of time complexity $\Theta(E+V)$) to be run on each vertex for every edge removal.
 - For a graph with E edges and V vertices, the overall time complexity will be $\Theta(EV(E+V))$

Neighborhood Overlap based Approach

Neighborhood Overlap (NOVER)

Neighborhood Overlap = $\frac{\text{number of nodes who are neighbors of both } A \text{ and } B}{\text{number of nodes who are neighbors of at least one of } A \text{ or } B}$

Note that one should not count neither A nor B as part of the neighbors in the denominator, and each node should be counted only once.

- | | |
|---------------------|---------------|
| 1 → {2, 3, 5, 6, 9} | 7 → {2, 4, 8} |
| 2 → {1, 4, 7} | 8 → {4, 7} |
| 3 → {1, 5, 6} | 9 → {1, 5} |
| 4 → {2, 7, 8} | |
| 5 → {1, 3, 6, 9} | |
| 6 → {1, 3, 5} | |

Edge	Union of Neighb.	Intersec.	NOVER
1 – 2	{3, 5, 6, 9, 4, 7}	{}	0/6 = 0.0
1 – 3	{2, 5, 6, 9}	{5, 6}	2/4 = 0.5
1 – 5	{2, 3, 6, 9}	{3, 6, 9}	3/4 = 0.75
1 – 6	{2, 3, 5, 9}	{3, 5}	2/4 = 0.5
1 – 9	{2, 3, 5, 6}	{5}	1/4 = 0.25
2 – 4	{1, 7, 8}	{7}	1/3 = 0.33
2 – 7	{1, 4, 8}	{4}	1/3 = 0.33
3 – 5	{1, 6, 9}	{1, 6}	2/3 = 0.67
3 – 6	{1, 5}	{1, 5}	1/1 = 1.0
4 – 7	{2, 8}	{2, 8}	2/2 = 1.0
4 – 8	{2, 7}	{7}	1/2 = 0.5
5 – 6	{1, 3, 9}	{1, 3}	2/3 = 0.67
5 – 9	{1, 3, 6}	{1}	1/3 = 0.33
7 – 8	{2, 4}	{4}	1/2 = 0.5

NOVER-based GN Algorithm

- At the beginning of each iteration, we compute the NOVER scores of the edges in the graph and remove the edge(s) with the smallest NOVER score(s).
 - If more than one edge has the smallest NOVER score, remove all such competing edges at the same time.
 - If the graph gets disconnected to two or more communities (components), we compute the total modularity score of the resulting communities
- Repeat the iterations until there are no more edges
- The partition (set of communities) with the total modularity score is the optimal partition.

NOVER-based GN Algorithm: Ex. 1

Iteration 1

Modularity (1, 3, 5, 6, 9)

$$\begin{aligned} \text{Mod}(1, 3) &= 1 - (5 \cdot 3) / (2 \cdot 14) = 0.46 \\ \text{Mod}(1, 5) &= 1 - (5 \cdot 4) / (2 \cdot 14) = 0.28 \\ \text{Mod}(1, 6) &= 1 - (5 \cdot 3) / (2 \cdot 14) = 0.46 \\ \text{Mod}(1, 9) &= 1 - (5 \cdot 2) / (2 \cdot 14) = 0.64 \\ \text{Mod}(3, 5) &= 1 - (3 \cdot 4) / (2 \cdot 14) = 0.57 \\ \text{Mod}(3, 6) &= 1 - (3 \cdot 3) / (2 \cdot 14) = 0.68 \\ \text{Mod}(3, 9) &= 0 - (3 \cdot 2) / (2 \cdot 14) = -0.21 \\ \text{Mod}(5, 6) &= 1 - (4 \cdot 3) / (2 \cdot 14) = 0.57 \\ \text{Mod}(5, 9) &= 1 - (4 \cdot 2) / (2 \cdot 14) = 0.71 \\ \text{Mod}(6, 9) &= 0 - (3 \cdot 2) / (2 \cdot 14) = -0.21 \end{aligned}$$

Modularity (1, 3, 5, 6, 9) = 3.95

Modularity (2, 4, 7, 8)

$$\begin{aligned} \text{Mod}(2, 4) &= 1 - (3 \cdot 3) / (2 \cdot 14) = 0.68 \\ \text{Mod}(2, 7) &= 1 - (3 \cdot 3) / (2 \cdot 14) = 0.68 \\ \text{Mod}(2, 8) &= 0 - (3 \cdot 2) / (2 \cdot 14) = -0.21 \\ \text{Mod}(4, 7) &= 1 - (3 \cdot 3) / (2 \cdot 14) = 0.68 \\ \text{Mod}(4, 8) &= 1 - (3 \cdot 2) / (2 \cdot 14) = 0.78 \\ \text{Mod}(7, 8) &= 1 - (3 \cdot 2) / (2 \cdot 14) = 0.78 \end{aligned}$$

Modularity (2, 4, 7, 8) = 3.39

Total Modularity Score = 7.34

NOVER-based GN Algorithm: Ex. 1 (2)

Modularity (1, 3, 5, 6)

$$\text{Mod}(1, 3) = 1 - (5 \cdot 3) / (2 \cdot 14) = 0.46$$

$$\text{Mod}(1, 5) = 1 - (5 \cdot 4) / (2 \cdot 14) = 0.28$$

$$\text{Mod}(1, 6) = 1 - (5 \cdot 3) / (2 \cdot 14) = 0.46$$

$$\text{Mod}(3, 5) = 1 - (3 \cdot 4) / (2 \cdot 14) = 0.57$$

$$\text{Mod}(3, 6) = 1 - (3 \cdot 3) / (2 \cdot 14) = 0.68$$

$$\text{Mod}(5, 6) = 1 - (4 \cdot 3) / (2 \cdot 14) = 0.57$$

$$\text{Modularity}(1, 3, 5, 6) = 3.02$$

Modularity (1, 2, 3, 4) = 3.57

Total Modularity Score = 6.44

Iteration 4: Total Modularity Score = 0.60

NOVER-based GN Alg. Ex-2(1)

**Optimal Partitioning
Into Communities**

**Total Modularity Score
6.44**

Weak Ties/Strong Ties

- An edge could be classified either as a weak tie or strong tie based on its NOVER score.
 - **An edge is a weak tie if its NOVER score is less than or equal to a threshold NOVER score**; otherwise, the edge is classified as a strong tie.
- Edges with lower NOVER scores bridge two different communities (as the end vertices of these edges have few common neighbors)
- Edges with higher NOVER scores are more likely to connect vertices within a community as the end vertices of these edges have more common neighbors.
- We will now see a simple community detection algorithm based on this notion of weak ties and strong ties.
 - Given a threshold NOVER score (or an appropriate score determined using the **Strong Triadic Closure Property**), all edges with NOVER score less than or equal to the threshold score will be classified as weak ties and the rest as strong ties.
 - It is just a one-step algorithm. We will remove all the weak ties and the components resulting from these removals will constitute the different communities.

Weak Ties-based Detection: Ex-1

Let threshold NOVER score be 0.4

Modularity(5,6,7,8)

$$\text{Mod}(5,6) = 1 - \frac{(5 \cdot 5)}{(2 \cdot 15)} = 0.17$$

$$\text{Mod}(5,7) = 1 - \frac{(3 \cdot 5)}{(2 \cdot 15)} = 0.50$$

$$\text{Mod}(5,8) = 1 - \frac{(3 \cdot 5)}{(2 \cdot 15)} = 0.50$$

$$\text{Mod}(6,7) = 1 - \frac{(3 \cdot 5)}{(2 \cdot 15)} = 0.50$$

$$\text{Mod}(6,8) = 1 - \frac{(3 \cdot 5)}{(2 \cdot 15)} = 0.50$$

$$\text{Mod}(7,8) = 1 - \frac{(3 \cdot 3)}{(2 \cdot 15)} = 0.70$$

$$\text{Modularity}(5, 6, 7, 8) = 2.87$$

$$\text{Mod}(7, 8) = 1 - \frac{(3 \cdot 2)}{(2 \cdot 14)} = 0.78$$

$$\text{Modularity}(4, 7, 8) = 2.24$$

$$\text{Total Modularity Score} = 5.26$$

Comparison of Algorithms: Ex-2

Weak Ties-based Algorithm
Total Modularity Score = 5.26

NOVER/BW-based Algorithm
Total Modularity Score = 7.34

Strong Triadic Closure Property

- If a node A has strong ties to two nodes B and C, then B and C are expected to have at least a weak tie between them.
 - More relevant for social networks
- A node that satisfies the above property for any of its two neighbors with which it has a strong tie is said to exhibit the Strong Triadic Closure property; otherwise the node is said to **VIOLATE** the property.
- A threshold NOVER score is considered appropriate only if the strong triadic closure property is satisfied for every node.
 - Smaller the threshold NOVER score, larger the chances for the property not being satisfied and vice-versa.

We will use the NOVER scores of the edges to pick a candidate threshold NOVER score

Let threshold NOVER score be 0.4

Strong Triadic Closure: Ex-1

Let threshold NOVER score be 0.0

Node	Strong Tie Neighbors	Weak Tie Neighbors	Strong Triadic Closure Property
1	3, 5, 6, 9	2	VIOLATED (no edge: 3, 9; 6, 9; etc)
2	4, 7,	1	YES
3	1, 5, 6	-	YES
4	2, 7, 8	-	VIOLATED (no edge between 2, 8)
5	1, 3, 6, 9	-	VIOLATED (no edge between 3, 9)
6	1, 3, 5	-	YES
7	2, 4, 8	-	VIOLATED (no edge between 2, 8)
8	4, 7	-	YES
9	5, 1	-	YES

Strong Triadic Closure: Ex-1 (1)

Let threshold NOVER score be 0.25

Node	Strong Tie Neighbors	Weak Tie Neighbors	Strong Triadic Closure Property
1	3, 5, 6	2, 9	YES
2	4, 7	1	YES
3	1, 5, 6	-	YES
4	2, 7, 8	-	VIOLATED (no edge between 2, 8)
5	1, 3, 6, 9	-	VIOLATED (no edge: 3, 9; 6, 9)
6	1, 3, 5	-	YES
7	2, 4, 8	-	VIOLATED (no edge between 2, 8)
8	4, 7	-	YES
9	5	1	N/A

Strong Triadic Closure: Ex-1 (2)

Let threshold NOVER score be 0.33

Node	Strong Tie Neighbors	Weak Tie Neighbors	Strong Triadic Closure Property
1	3, 5, 6	2, 9	N/A
2	-	1, 4, 7	N/A
3	1, 5, 6	-	YES
4	7, 8	2	YES
5	1, 3, 6	9	YES
6	1, 3, 5	-	YES
7	4, 8	2	YES
8	4, 7	-	YES
9	-	1, 5	N/A

Strong Triadic Closure: Ex-1 (3)

Let threshold NOVER score be 0.33

Weak Ties-based Algorithm; Total Modularity Score = 5.26

Strong Triadic Closure: Ex-2

Trial # 1

Threshold NOVER Score = 0.2

Strong Triadic Closure: Ex-2 (1)

Trial # 1
Threshold NOVER Score = 0.2

Node	Strong Tie Neighbors	Weak Tie Neighbors	Strong Tri. Clos. Prop.
1	2, 3, 4	-	YES
2	1, 3, 4	-	YES
3	1, 2, 4	9	YES
4	1, 2, 3	9	YES
5	6, 7, 8	-	YES
6	5, 7, 8	-	YES
7	5, 6, 8	13	YES
8	5, 6, 7	13	YES
9	10	3, 4, 11	N/A
10	9, 11	-	YES
11	10, 12	9, 13	VIOLATED
12	11, 13	-	YES
13	12	11, 8, 7	N/A

Strong Triadic Closure: Ex-2 (2)

Trial # 2

Threshold NOVER Score = 0.33

Strong Triadic Closure: Ex-2 (3)

Trial # 2

Threshold NOVER Score = 0.33

Node	Strong Tie Neighbors	Weak Tie Neighbors	Strong Tri. Clos. Prop.
1	2, 3, 4	-	YES
2	1, 3, 4	-	YES
3	1, 2, 4	9	YES
4	1, 2, 3	9	YES
5	6, 7, 8	-	YES
6	5, 7, 8	-	YES
7	5, 6, 8	13	YES
8	5, 6, 7	13	YES
9	-	10, 3, 4, 11	N/A
10	-	9, 11	N/A
11	-	10, 12, 9, 13	N/A
12	-	11, 13	N/A
13	-	12, 11, 8, 7	N/A

Since the Strong Triadic Closure Property is NOT VIOLATED for any node, We will use the Threshold NOVER Score = 0.33.

Weak Ties-based Detection: Ex-2

Modularity (1, 2, 3, 4)

Mod (1, 2) = 0.795

Mod (1, 3) = 0.727

Mod (1, 4) = 0.727

Mod (2, 3) = 0.727

Mod (2, 4) = 0.727

Mod (3, 4) = 0.636

Modularity (1, 2, 3, 4) = 4.339

Modularity (5, 6, 7, 8) = 4.339

Total Modularity Score = 8.678

NOVER-based GN: Ex-2

Modularity (1, 2, 3, 4) = 4.339
 Modularity (5, 6, 7, 8) = 4.339

Modularity (9, 10, 11, 12, 13)

Mod (9, 10) = 0.818
 Mod (9, 11) = 0.636
 Mod (9, 12) = -0.182
 Mod (9, 13) = -0.364
 Mod (10, 11) = 0.818
 Mod (10, 12) = -0.091
 Mod (10, 13) = -0.182

Mod (11, 12) = 0.818
 Mod (11, 13) = 0.636
 Mod (12, 13) = 0.818
Modularity (9, ..., 13)
= 3.725

Total Modularity
= 12.403

NOVER-based GN: Ex-2 (1)

Iteration 2

Total Modularity = 0

Homophily-based Community Detection

Homophily

- In social networks, people tend to associate more closely with people who are similar to each other with respect to race, ethnicity, job, home town, etc (offline characteristics).
 - Homophily
- The community detection algorithms we have seen until now do not take the offline characteristics of the nodes into consideration.
- We will now assume the offline info of the nodes are available and we make use of this info for community detection.
- If p and q are the fractions of nodes of certain type in a network, then if the links in the network are randomly distributed (without taking the type of the nodes), the fraction of the links expected to connect these two types of nodes is $2pq$.
- If the actual fraction of links in a network connecting nodes of two different types is less than $2pq$, we say the network exhibits a homophily, and the nodes cannot be part of one community.
- If the actual fraction of links in a network connecting nodes of two different types is greater than or equal to $2pq$, then the network is not considered to exhibit homophily, and the nodes are considered to be part of just one single community.

Measuring Homophily

p and q are the fractions of nodes of two different types

If two sets of nodes are to be of their own community (i.e., for HOMOPHILY to exist), we would expect a relatively lower number of cross-community links between them.

FOR HOMOPHILY TO EXIST,

The actual fraction of cross-community links between two different communities should be less than the expected fraction of links between the two sets of nodes if they were to exist as one community.

Homophily: Example-1

Nodes = 10

Links = Sum of Degrees / 2 = 20

Male Students: 1, 2, 3, 4, 7, 8

Female Students: 5, 6, 9, 10

Fraction of Male Nodes: $6/10 = 0.6$

Fraction of Female Nodes: $4/10 = 0.4$

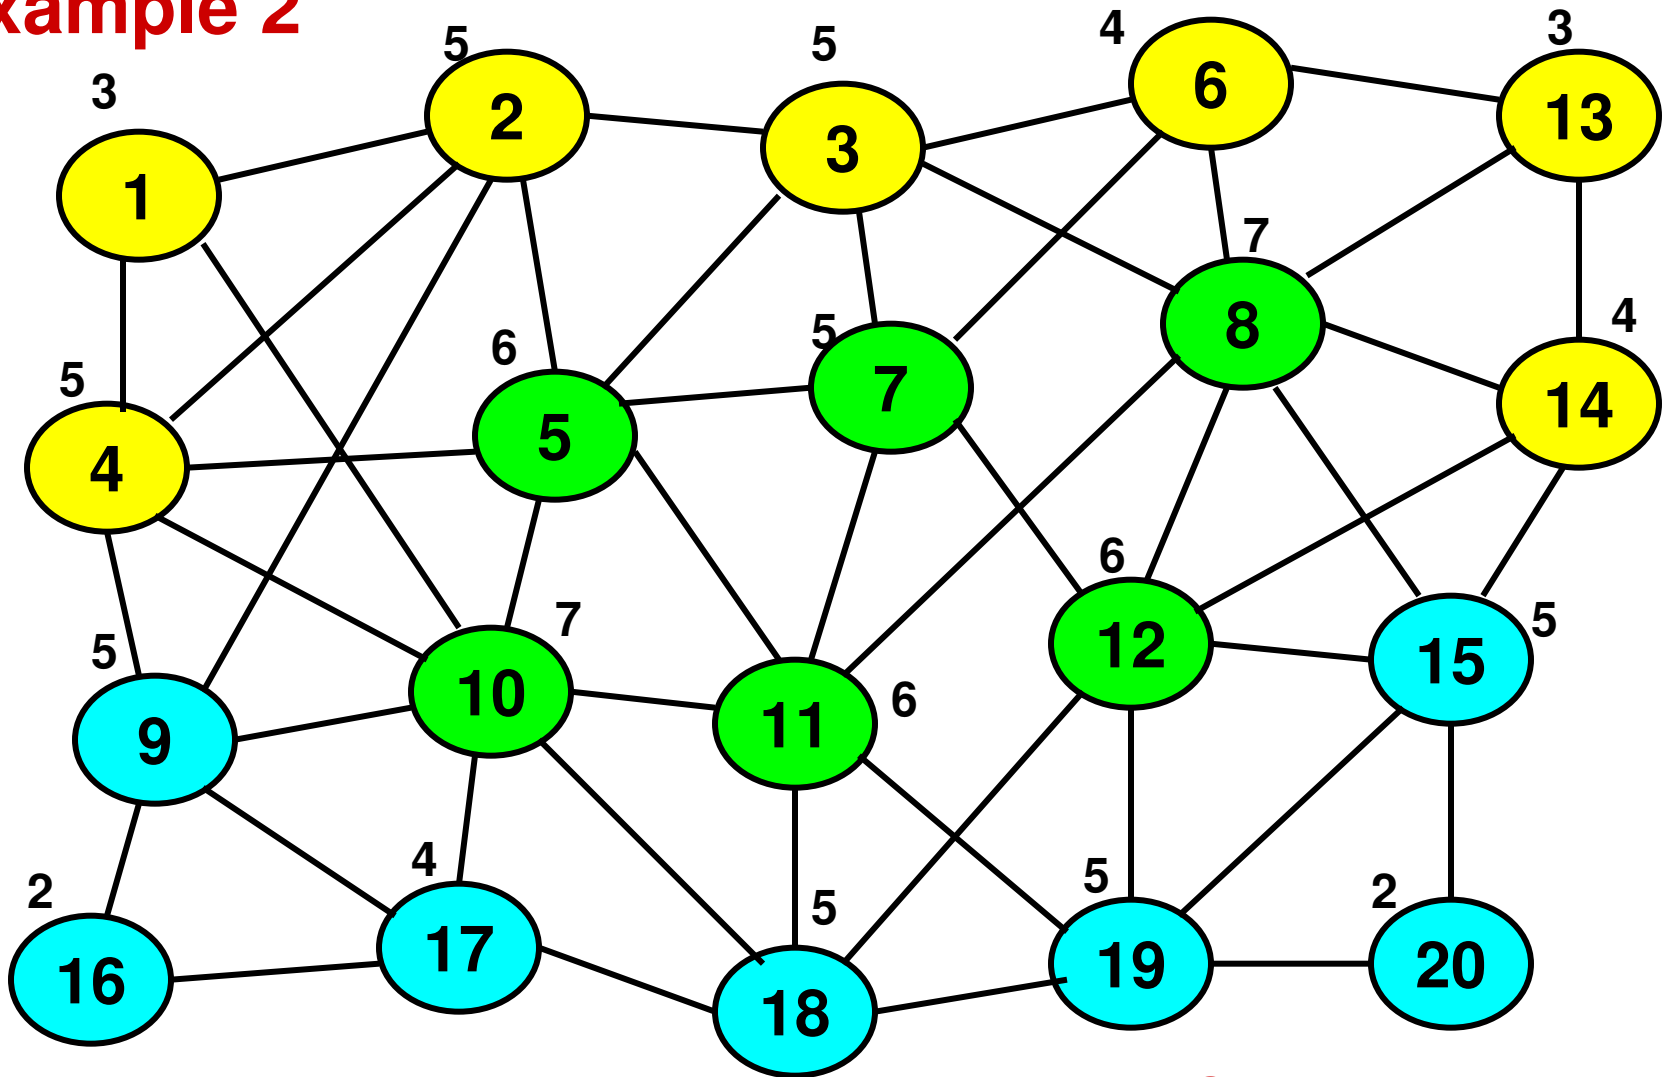

Expected Fraction of Male-Female Links = $2 * 0.6 * 0.4 = 0.48$

Actual Links between Male and Female nodes: 6

Actual Fraction of Male-Female Links = $6/20 = 0.3 < 0.48$
Hence, there is HOMOPHILY.

Example 2

Links = Sum of Degrees / 2 = 47

Asian Origin Vertices: 5, 7, 8, 10, 11, 12

Caucasian Origin Vertices: 1, 2, 3, 4, 6, 13, 14

Hispanic Origin Vertices: 9, 15, 16, 17, 18, 19, 20

(A): $6/20 = 0.3$

(C): $7/20 = 0.35$

(H): $7/20 = 0.35$

Example 2(1)

5, 7, 8, 10, 11, 12
1, 2, 3, 4, 6, 13, 14
9, 15, 16, 17, 18, 19, 20

(A): $6/20 = 0.3$
(C): $7/20 = 0.35$
(H): $7/20 = 0.35$

Fraction of A-H Links = $9/47 = 0.19$
 $< 2 * A * H = 2 * 0.3 * 0.35 = 0.21$
Hence, the Asians and Hispanics
exist as two different communities
and NOT together.

Example 2(2)

A-C Links: 12

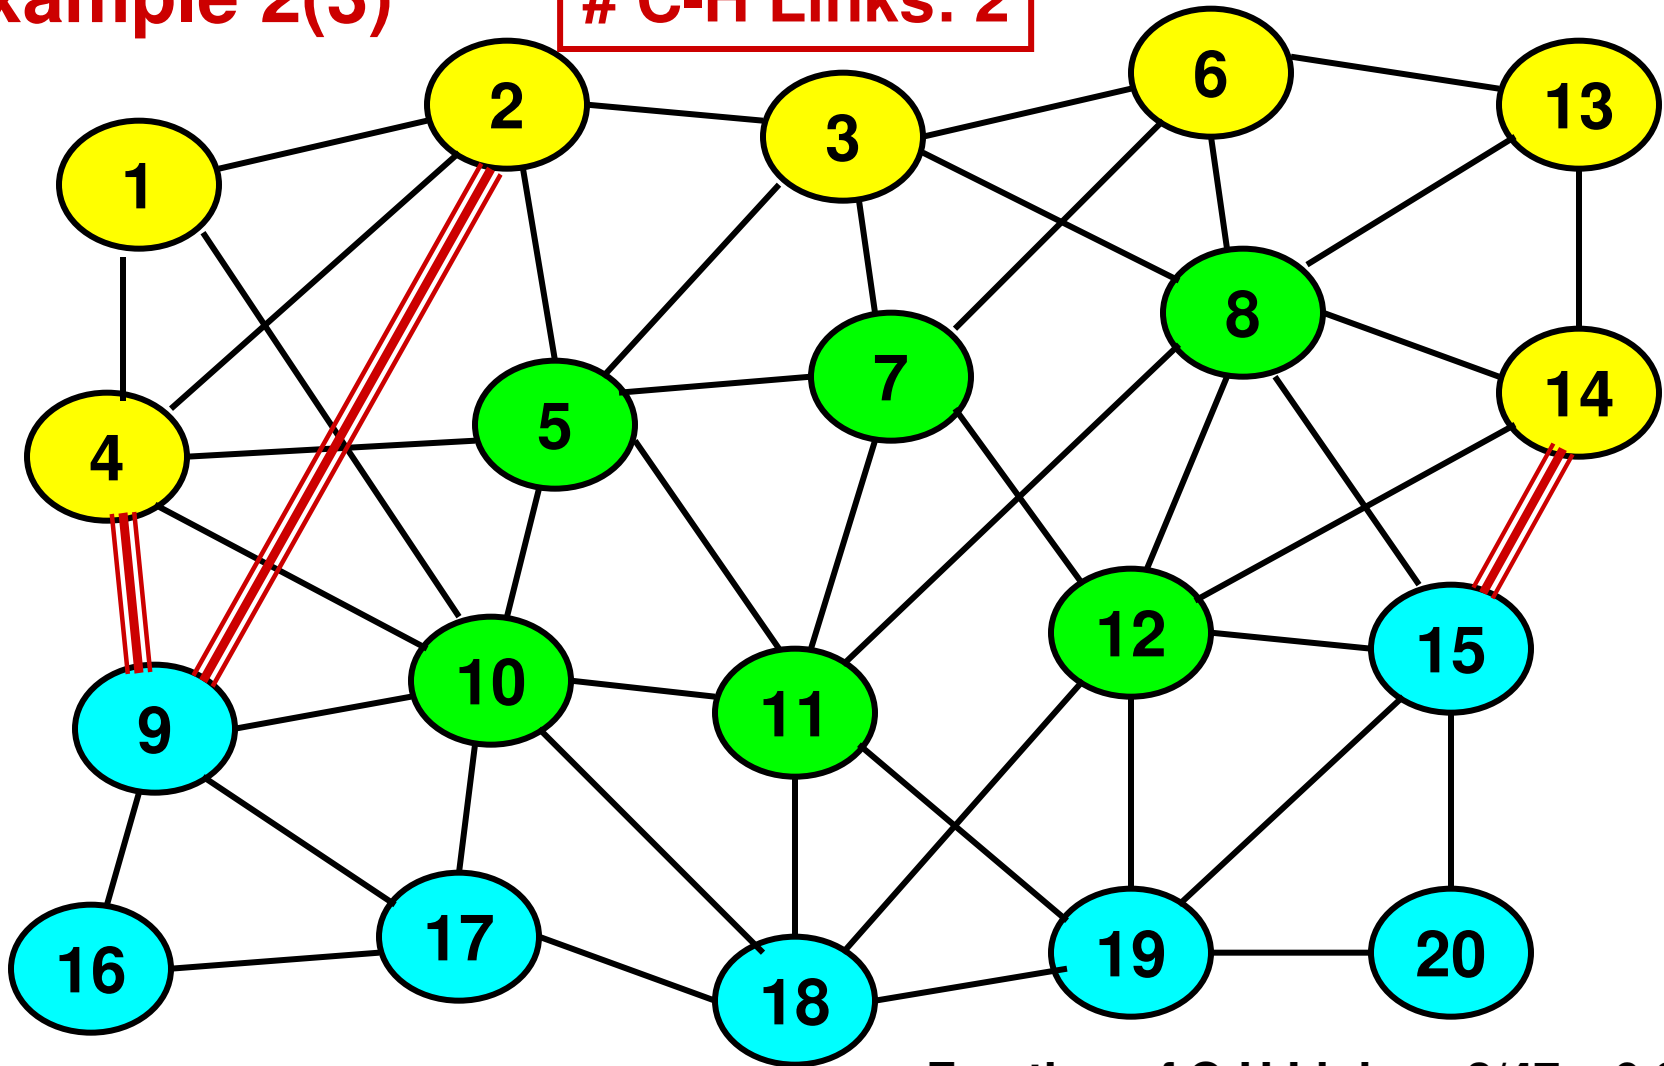

5, 7, 8, 10, 11, 12
1, 2, 3, 4, 6, 13, 14
9, 15, 16, 17, 18, 19, 20

(A): $6/20 = 0.3$
(C): $7/20 = 0.35$
(H): $7/20 = 0.35$

Fraction of A-C Links = $12/47 = 0.26$
 $> 2 * A * C = 2 * 0.3 * 0.35 = 0.21$
Hence, the Asians and Caucasians
DO NOT exist as two different
communities.

Example 2(3)

C-H Links: 2

5, 7, 8, 10, 11, 12

1, 2, 3, 4, 6, 13, 14

9, 15, 16, 17, 18, 19, 20

$$(A): 6/20 = 0.3$$

$$(C): 7/20 = 0.35$$

$$(H): 7/20 = 0.35$$

$$\text{Fraction of C-H Links} = 3/47 = 0.064$$

$$< 2 * C * H = 2 * 0.35 * 0.35 = 0.245$$

Hence, the Caucasians and Hispanics exist as two different communities and NOT together.

Example 2(4)

Links = Sum of Degrees / 2 = 47

Asian Origin Vertices: 5, 7, 8, 10, 11, 12

(A): $6/20 = 0.3$

Caucasian Origin Vertices: 1, 2, 3, 4, 6, 13, 14

(C): $7/20 = 0.35$

Hispanic Origin Vertices: 9, 15, 16, 17, 18, 19, 20

(H): $7/20 = 0.35$
